SESSION ID:
SEC-F01

The New Key Management: Unlocking the Safeguards of Keeping Keys Private

Jono Bergquist

Solutions Engineering Lead -

APJ

CloudFlare

CHANGE

Challenge today's security thinking

Outline

- ◆ Why application-level TLS is important
- ◆ Key management is the hardest part of TLS
- ◆ How to use trusted computing for cryptography
- ◆ Solving TLS key management with TPMs

The perimeter is porous

Traditional Network Security Topology

Internet VPN

Traditional Network Security Topology

- ◆ Multiple internal services
 - ◆ Databases with customer data
 - ◆ Employee portals
- ◆ Cross-datacenter communication across Internet via **VPN**
 - ◆ All or nothing access

The perimeter is porous - VULCANDEATHGRIP

Traditional network topology

- ◆ VPN compromise makes application-to-application data readable

Web Application Security Topology

Edge Network

Mobile network

The modern corporate network

- ◆ Components
 - ◆ Website hosted on a SaaS/IaaS platform
 - ◆ Core business services
 - ◆ Loosely affiliated group of services hosted by third parties

The modern corporate network

- ◆ Access control
 - ◆ Third-party services
 - ◆ Federated identity (SAML, OAuth, etc.)
 - ◆ Single sign-on
 - ◆ Service-to-service authentication
 - ◆ Implicit via VPN
 - ◆ Token-based

Examples of application-to-application data

- ◆ Data breaches
 - ◆ User passwords
 - ◆ Customer data
 - ◆ HR Data
 - ◆ Customer lists
 - ◆ Proprietary intellectual property
- ◆ All from applications inside the network

The modern corporate network

- ◆ The perimeter is fuzzily defined
- ◆ Move security to a higher level in the stack?

Application-layer Encryption

Encryption

- ◆ Corporate data should be encrypted

Encryption

- ◆ ...at rest
- ◆ ...in transit
- ◆ ...with authentication

Layer 3 Encryption

- ◆ IPsec tunnel/VPN
 - ◆ Expensive hardware
 - ◆ Does not scale to edge networks
 - ◆ Trust everyone

Layer 5/6 Encryption

- ◆ Kerberos
 - ◆ Web applications do not use it
- ◆ Transport Layer Security
 - ◆ Widely supported among a range of applications

Transport Layer Security (TLS)

- ◆ The protocol formerly known as SSL
- ◆ Provides server-to-server encryption
- ◆ Authentication via certificate validation

- ◆ Advantages
 - ◆ Cheap in software on modern processors (AES-NI)
 - ◆ Widely supported in service oriented software

Transport Layer Security (TLS)

- ◆ Challenges for application-to-application TLS
 - ◆ Building a system of trust
 - ◆ Key management

Building trust in applications

TLS without certificate validation

- ◆ Traditional man-in-the-middle attack

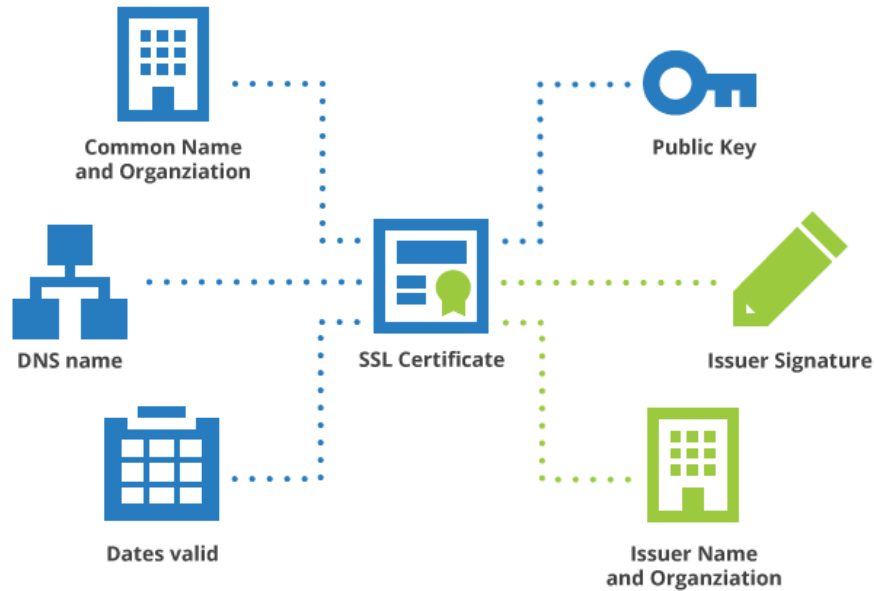

Trust Models for TLS

- ◆ Public Key Infrastructure model
- ◆ Each application has:
 - ◆ Public X.509 certificate
 - ◆ Corresponding private key

X.509 Public Key Infrastructure

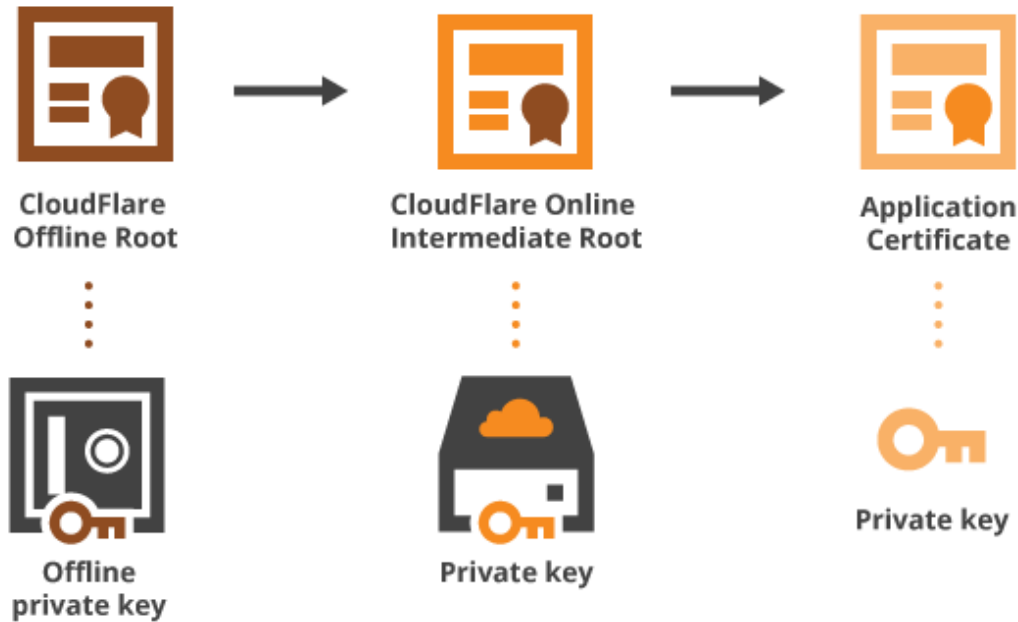

The anatomy of a certificate

Trust Models for TLS

- ◆ Session key used to encrypt connection
- ◆ Private key used to
 - ◆ Prove ownership of certificate
 - ◆ Authenticate session establishment
- ◆ Validate certificates with a chain of trust

Certificate chain of trust

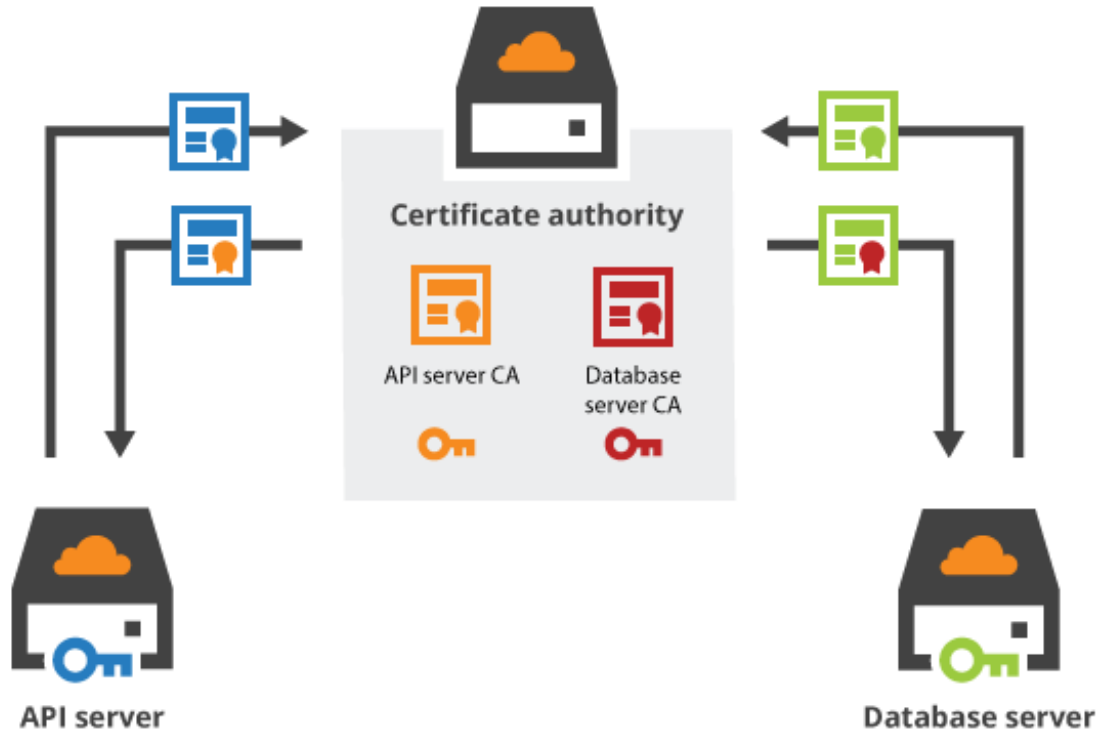

PKI-enabled applications

- ◆ Database access
- ◆ Business services
- ◆ Mobile applications

Private PKI

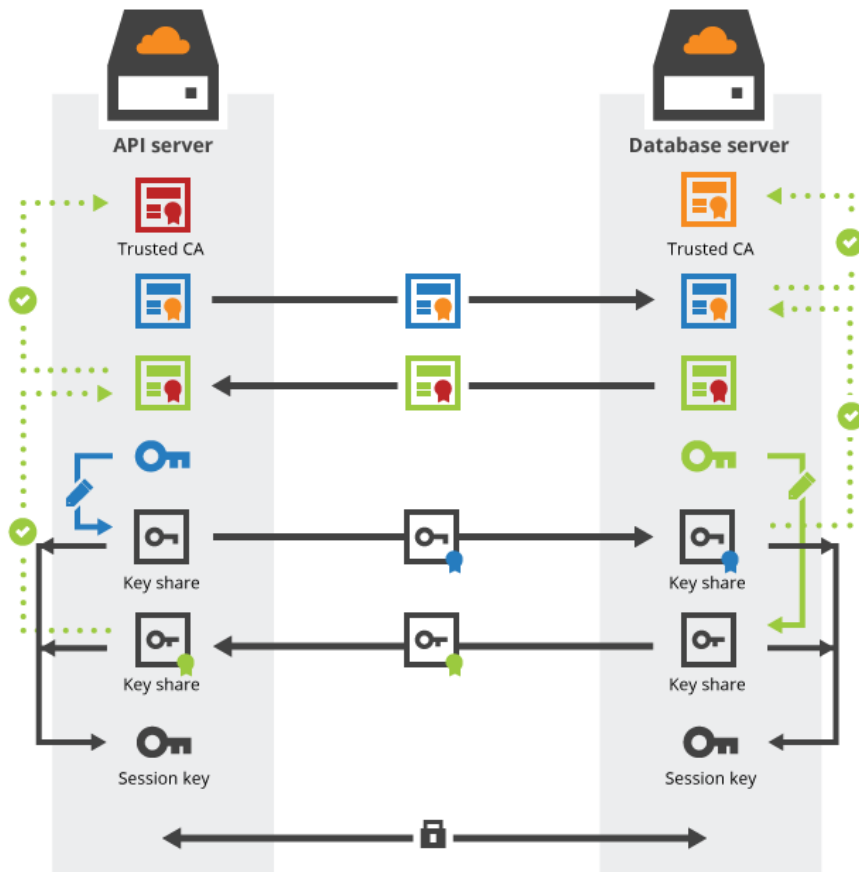

- ◆ Run your own internal Certificate Authority
- ◆ Generate keys locally on endpoints
- ◆ Use internal CA to create certificates

Different CAs for different domains

Service to service communication

With TLS mutual authentication

Tools

- ◆ OpenSSL
- ◆ CFSSL
 - ◆ CloudFlare's open source CA software
- ◆ pki.io
- ◆ EJBCA
- ◆ Commercial options

Advantages

- ◆ Application data is encrypted in transit
- ◆ Requests are authenticated
- ◆ VPN failure is no longer catastrophic

The bootstrap problem

- ◆ Enrolling new servers
- ◆ Authenticating requests for certificates

Dangers

- ◆ Keys live in memory and on disk
- ◆ Can be stolen and applications impersonated

Trusting trusted computing

Protecting keys on servers

- ◆ Keep keys in hardware instead of software
- ◆ Each machine needs its own hardware
 - ◆ HSMs are prohibitively expensive
 - ◆ TPMs fit the bill (\$15-\$30 each)

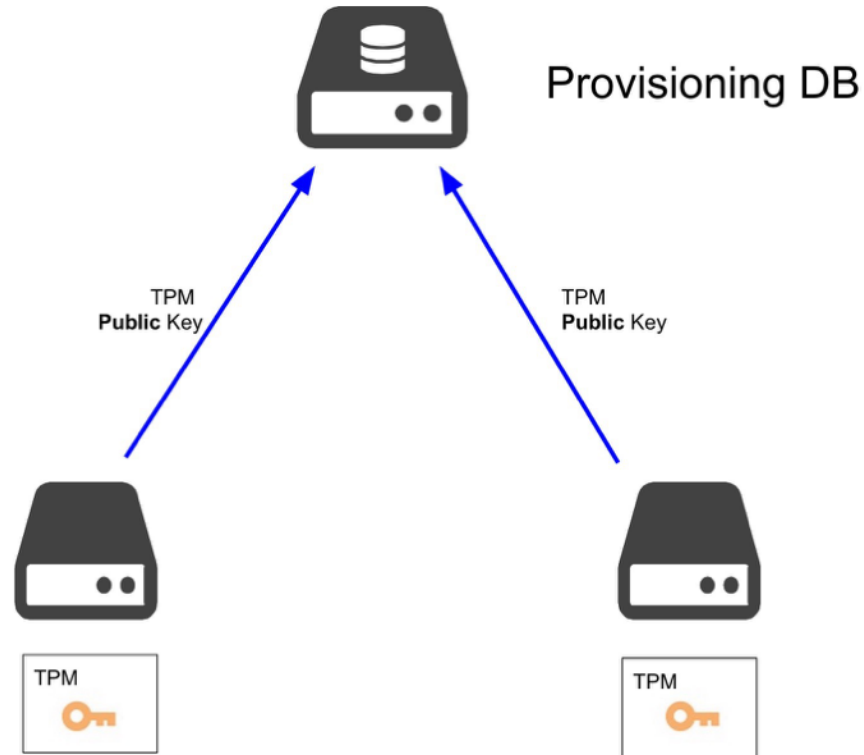

Trusted Platform Module

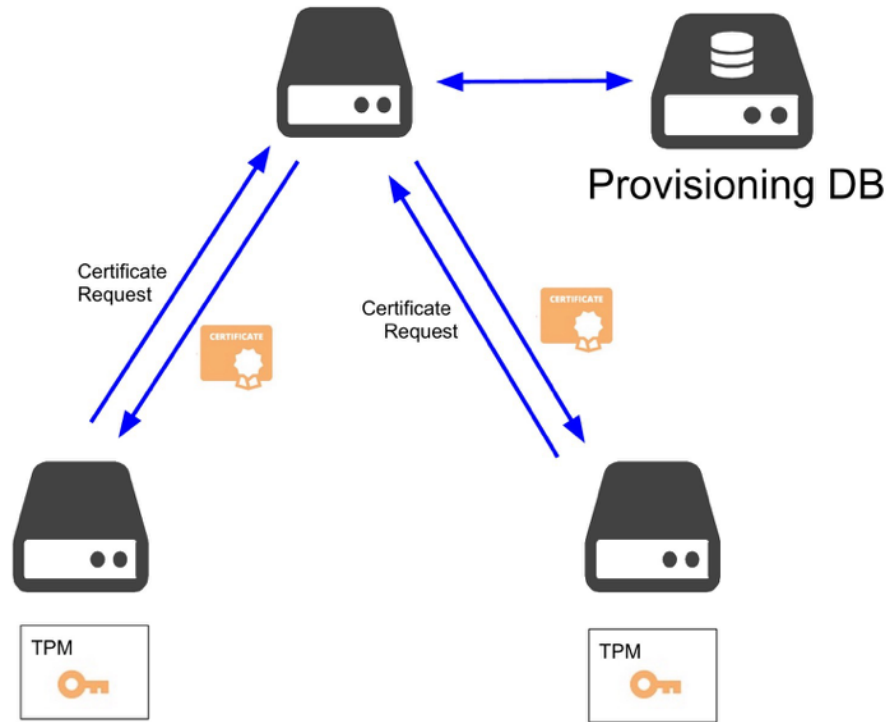

Trusted Platform Module

- ◆ Most commonly used for Windows trusted boot
- ◆ List of features of TPM 1.2
 - ◆ Measured Boot
 - ◆ Random number generation
 - ◆ RSA 2048 private keys

Machine provisioning

Certificate issuance

Benefits

- ◆ Keys do not live in software
 - ◆ Safe from memory access (Heartbleed, DMA)
 - ◆ Safe from theft (TPM locked)
 - ◆ Safe from impersonation

Drawbacks

- ◆ Not all software supports TPM crypto
- ◆ It is sloooooow

Simple guide

How to set up secure application transport

- ◆ Create your own CA on a trusted machine or HSM
- ◆ Create a key on your device TPM
- ◆ Use TPM to create a certificate signing request (CSR)
- ◆ Create certificate from CSR with CA
- ◆ Configure web server to use certificate and TPM for private key operation
- ◆ Go for it!

Action

What you can do right now

- ◆ Do your applications speak TLS?
- ◆ If so, are they doing certificate validation?
- ◆ Where are the private keys stored and managed?

What you can do in the next months

- ◆ Consider your attacker is an insider
 - ◆ Which backend applications accept connections?
- ◆ Suppose there is a firewall or VPN misconfiguration
 - ◆ Is any data is exposed?
 - ◆ What authentication is your database using?

What you can do in the next months

- ◆ Once TLS is activated, make sure it is configured properly
 - ◆ Certificate validation
 - ◆ TLS 1.2
- ◆ Start using C or Go services built on open source tools
